

REALITY OF TIME

S. C. Tiwari

*Institute of Natural Philosophy
c/o 1 Kusum Kutir, Mahamanapuri, Varanasi-221 005, India.*

The meaning of instantaneous action at a distance is elucidated. It is shown that the absence of a medium to transmit action (usually referred to as AAD in the literature) and instantaneous action are not identical. Since the term “instantaneous” is incompatible with relativity and field theory, a critique is presented on the concept of time in relativity. It is argued that relativity does not deal with the nature of time. Physical reality of the absolute time is envisaged, and instantaneous action is proposed to be a natural consequence of it. Possibly gravity is such kind of a force, however the electromagnetic force, though envisaged as direct particle interaction (i.e. without intermediary fields) can not be instantaneous.

1. Introduction

Sense impressions or empirical observations seem to suggest a dichotomy of the physical world into isolated independently existing objects and a physical mechanism to relate observed mutual influences between them. In modern perspective one finds expression of this dichotomy in terms of elementary particles and their interactions (believed to be the four fundamental forces of nature). Philosophical urge to seek connectedness with the separation, and wholeness within the parts have led to the conception of physical reality with intrinsic duality. Primarily due to this, both action-at-a-distance (AAD) and field theory possess a sort of indistinguishable character as far as the verifiable experimental consequences are concerned. The main aim of this article is to elucidate the proposition that the nature of time might play a fundamental role to throw light on the meaning of instantaneous AAD. To delineate the basic problems a brief commentary on AAD is presented in the next section. The concept of time is discussed in section 3. In the final section the idea of the absolute time is presented, and its implications on AAD versus field theory are outlined.

2. Review of Action-At-A-Distance

The idea of AAD is commonly attributed to Newton, however, Cajori in the appendix to Newton's *Principia* [1] argues that the doctrine of AAD belongs to Cotes, not to Newton. He quotes Maxwell to support his claim, and refers to a letter from Newton:

“That gravity should be innate, inherent and essential to matter, so that one body may act upon another at a distance through a vacuum, without the mediation of anything else, by and through which their action and force may be conveyed from one to another, is to me so great an absurdity, that I believe no man, who has in philosophical matters a competent faculty of thinking, can ever fall into it. Gravity must be caused by an agent according to certain laws, but whether this agent is material or immaterial, I have left to the consideration of my readers.”

The transition from ‘absence of a medium’ to ‘instantaneous action’ is not straightforward, in fact the discoveries of force laws in electricity and magnetism, and analogy with Newton's gravitational force law led to a subtle change in the interpretation. Newtonian interpretation suggests that a medium to transmit force is necessary, but it can happen instantaneously. Maxwell field equations, on the other hand give rise to wave equations such that the fields have finite velocity of propagation. For an electrostatic field of a charged body an additional feature emerges: the longitudinal waves. To see this, the electrostatic potential $\Phi(\mathbf{r})$ is expanded in a Fourier integral, and the Poisson equation is used to obtain the following relation for a point charge

$$\Phi_{\mathbf{k}} = \frac{4\pi e}{k^2}, \quad (1)$$

here $\Phi_{\mathbf{k}}$ is the Fourier component of a zero frequency wave with wave vector $\mathbf{k}$. Fourier components of electric field vector can be calculated using equation (1) to give

$$\mathbf{E}_{\mathbf{k}} = -i \frac{4\pi e \mathbf{k}}{k^2}. \quad (2)$$

Since $\mathbf{E}_{\mathbf{k}}$ is parallel to $\mathbf{k}$, the Coulomb field has longitudinal waves, and the time independence is interpreted to imply instantaneous AAD. Generalizing the Poisson equation to in-homogeneous wave equation the action propagating with the velocity of light is obtained. One can formulate a theory without introducing the fields using the interaction action integral:

$$\mathcal{L}_I = \frac{1}{2} \sum_{i,j=1(i \neq j)}^n e_i e_j \int \frac{dz_i^\mu}{d\lambda_i} \frac{dz_j^\mu}{d\lambda_j} \delta[(z_i - z_j)^2] d\lambda_i d\lambda_j. \quad (3)$$

This type of theory is called AAD because no mediating agency is required to carry the interaction [2]. Here λ_i is a parameter used to label the worldline z_i^μ of i -th

charged particle e_i of the n -particle system. Delta-function in (3) ensures that for $\mathcal{L}_I$ to be non-vanishing the “worldlines” are connected by light signal, and self interaction is absent as $i \neq j$. The statement in [3] “*strictly, the phrase ‘action at a distance’ should be changed to ‘action at no distance’*” shows that such theories are not genuine AAD. Moreover, direct particle fields introduced in this approach, and the perfect absorption by the rest of the universe postulated by Wheeler and Feynmann [4] though explain the existence of radiation overcoming the difficulties faced by the Schwarzschild-Tetrode-Fokker theory, the resulting scheme is more akin to field theory than the AAD. Ironically the delta-functions in field theories serve the purpose of bringing in particulate aspect as field singularities while in this version of the AAD they incorporate fields. The simplest way to recognize this fact is to affect the variation on $\mathcal{L}_I$, and define the direct potential as

$$A_i^\mu(z_k) = e_i \int_{-\infty}^{+\infty} \delta[(z_k - z_i)^2] \frac{dz_i^\mu}{d\lambda_i} d\lambda_i. \quad (4)$$

These potentials satisfy the inhomogeneous wave equation, and depend on the sources more like defining relations without independent degrees of freedom. The details can be seen in [2]. The application of this approach to derive the equation of motion of electron has been extensively discussed in the literature. An important critique by Havas [5] deserves attention comparing Dirac’s theory with this theory arriving at the conclusion that experimentally the two theories are “indistinguishable”.

An important problem which has a bearing on this discussion, the essence of which was perceived by Planck studying the matter-radiation interaction arises in the quantum electrodynamics. Einstein’s light quantum hypothesis and field theory seemed irreconcilable to him, and led to his second and third theories [6]. In 1911 he proposed that while emission of radiation occurs discontinuously in quanta, absorption is a continuous process. In this second theory, a remarkable result followed, namely the appearance of zero-point energy of the oscillator. In 1914 he revised his ideas and proposed his third theory: the emission and absorption are both continuous, the discrete energy exchange takes place only during collisions between the oscillators and free particles. In the language of quantum electrodynamics, the interaction is described in terms of the exchange of photons i.e. the carriers of the interaction. Following Planck we may ask if the photon acquires continuous field property once emitted from the charged body. Or is it possible to formulate a complete particle theory totally dispensing with the continuous electromagnetic fields, and employing only photons?

Present brief commentary shows that the role of time, the nature of sources and the understanding of continuum are fundamental issues to be addressed for making

further decisive progress in resolving the debate on the mechanism of interaction(s), and that one must be careful as regards to the version of AAD one is referring to.

3. The Concept of Time: A Critique

Relativist's world-view is claimed to have revolutionized our thinking on space and time, radically altering the classical Newtonian system. Is it true? To answer this question, first I will base my discussion on Einstein's own exposition of his theory of relativity[7]. Special theory of relativity (STR) asserts the following: (1) The laws of nature are in concordance for all inertial frames, (2) the hypothesis of the absolute character of time is discarded, (3) simultaneity has no objective meaning, and (4) four dimensional space-time has absolute character, and has physical reality. Einstein does not define motion, and assuming uniform motion postulates inertial frames (K). Absolute time, according to him has the meaning: "*the time of an event in K' is the same as the time in K* ". This absolute time makes physical sense if instantaneous signals exist, and the state of motion of a clock has no effect on its rate. Since no such signals exist, a scheme for time measurement is suggested postulating the constancy of the velocity of light in vacuum. In a frame K , clocks U_n relatively at rest are placed at all points of space. A light signal from one of the clocks U_k sent at the instant t_k travels in vacuum to U_l placed at a distance d_{kl} which is now set to indicate the time

$$t_l = t_k + \frac{d_{kl}}{c}. \quad (5)$$

In all inertial systems the clocks are regulated in this manner. Simultaneity becomes relative, and time specification depends on the space of reference. The constancy of the velocity of light in all inertial frames leads to a geometrical invariant 4-dimensional length

$$ds^2 = dr^2 - c^2 dt^2 = 0. \quad (6)$$

The step from (6) to arbitrary non-zero ds^2 being invariant invokes the assumption of the directional independence in space. In analogy with the Euclidean geometry, the world-geometry in STR is postulated to be 4-dimensional space-time continuum. In contrast to Einstein, Newton is careful to distinguish two kinds of space, time and motion: absolute and relative. Absolute (relative) motion is the translation of a body from one absolute (relative) place into another. Absolute time, by its own nature flows equably without relation to anything external. Relative or common time is some sensible and external measure of duration by means of motion [1]. Einstein is concerned with this relative time, and the process of its measurement. What is the meaning of the instant t_k recorded by the clock U_k ? Obviously it is implicit assumption that there is something called time, and that there exists earlier and later ordering of time.

Criticisms/analyses by other authors have been presented in some of my earlier papers [8], however, a brief discussion may be pertinent at this point. Reichenbach using light and matter axioms offers an axiomatization of STR with space, time and motion as presupposed concepts [9]. He says that modern epistemology has shown that Kant's intuitive time is untenable, and attempts to define time at a point P without invoking the direct perception of time flow. First a signal is defined as a physical process which can be marked at a real point P , and can be transmitted to another point P' where the mark can be recognized. A signal marked at P is sent to some other point P' , again marked at P' returns to P . The detection of two marks ascertains the temporal sequence at P . It is logically unsatisfactory to consider another distant point P' in order to define the time order at P . Not only this, Reichenbach ignores the interaction duration for the marking process, and the memory and logical decision making capability of the detection device.

Bunge's aim is to free STR from misinterpretations [10]. Time, Euclidean space and inertial frames belong to proto-physics, and the role of electromagnetic fields is stressed by him. Newtonian absolute time is criticized as being metaphorical and hanging in the midst of nothingness. 'Flows equably' implies constant rate which in turn involves the notion of time, and hence there is a circularity in this definition. However, Bunge's analysis does not provide any new insight into the meaning of time, and temporal order as well as protophysics remain unexplained.

Thus relativity is founded on motion, inertial system and relative time of Newton with a new measurement convention using light signal, see also Dingle's interpretation [11]. It does not deal with the absolute time and its nature. I have argued earlier [8] that it is not merely a question of philosophical taste or pure reasoning, the life-time of an unstable particle changing with velocity poses a paradox if relativistic time dilation is identified with this. The decay being an irreversible process, life-time corresponds to a unidirectional lapse of time; on the other hand time dilation is based on time inversion symmetrical kinematics. Therefore, the question of the physical reality of time is not an empty issue; we address this problem in the next section.

4. Absolute Time: Physical Reality

The basic idea put forward in late 1970s [12] is very simple: time is the primeval cause of the manifest universe, and time flow is regulated by a Cosmic principle. To make physical sense out of it, and to relate it with the contemporary understanding and the language of discourse is, however not easy. We postulate an inert and unobservable source space which is continuously being changed to observable active space (or manifest universe) by the action of time. The possible active states are proposed to be those of rotation and expansion. An alternative definition of source

space is the rest of the space other than the universe. The universe spins with reference to the source space and expands into it. The cause of rotation and expansion is the absolute time, the duration of which is determined by cosmic motion. Universality of the absolute time flow entails space continuum for the whole of the universe. The rotation determines periodicity of the cosmic clock, and expansion makes the time to be inherently unidirectional. Time reversal is non-existent, and space-time continuum has no meaning for this absolute time. Though the spatial changes within the universe are correlated with the absolute time frame as far as earlier and later ordering is concerned, one is free to setup convenient definition and measurement setup for relative or common time to describe such spatial relations.

In a somewhat abstract construction following[8] the absolute and common time can be explained noting that any measurement in physics ultimately reduces to a counting of spatial relations in terms of a reference standard unit, D . For unchanging spatial relations between any two points in the space (a rigid structure) one can use a standard scale, but this method has to be modified once changing spatial relations are allowed. A reference unit C possessing intrinsic uniform spatial relation, if it exists may replace the scale for calibrating changing spatial relations. Let us imagine a space S within which occur continuous flow of space points thereby leading to changing spatial relations. Note that this description endows the space S an active role i.e. moving points. One can classify sets of uniform changing relations, I , and admit the possibility of reversible changes. To reduce the complexity of the description an order parameter, t may be introduced, and calibrated using the device C . Let us now suppose some 'external' change on the whole of the space S such that this regulates the changes within S i.e. there is a harmony between the two, and this change, denoted by T takes place uniformly and unidirectionally without relation to anything 'inside' S . Translating this description to physical situation, S is the universe, t is common time, I is the inertial frames, C is the light signal, and T is the absolute time. The parameter t merely represents a convenient mathematical definition to coordinate the changes in spatial relations, and admits the transformation $t \rightarrow -t$, but it is unphysical. The parameter t acquires physical meaning only when it is related with unidirectional flow T .

Inadvertently identity of mathematical parameter and physical common time has been assumed since the time of Newton resulting into unexplainable possible physical situations. In STR the light cone and its future and past division illustrates one of the problems: equation (6) is valid for mathematical time t , but to relate it with T one invokes causality and impossibility of any material particle attaining or exceeding the velocity of light. In general relativity the things are not so simple since the metric in

$$ds^2 = g_{\mu\nu} dx^\mu dx^\nu \quad (7)$$

will change the light cone from one space-time point to another. Usually one defines locally special relativistic time in the GR, but near massive bodies this procedure is not applicable. Singularities as space-time edge appear to be distinct at the beginning (e.g. big-bang creation) and end (collapse of a massive object to a black hole), see [13]. Does it indicate arrow of time? The question itself becomes meaningless as shown by Godel's solution [14]. He points out that relativity of simultaneity implies that lapse of time has no objective meaning [15]. In cosmological models based on GR which appear to be consistent with the observations, a time common to the whole universe can be defined. Jeans took it as supporting the idea of an absolute lapse of time, but Godel argues that there do exist cosmological solutions which allow one to travel in the past, present and future. The assumed metric is a solution of the field equation

$$R_{\mu\nu} - \frac{1}{2}g_{\mu\nu}R = 8\pi k\rho u_\mu u_\nu + \lambda g_{\mu\nu}. \quad (8)$$

Besides the matter energy-momentum tensor, it has the cosmological constant term first introduced by Einstein for static universe, but with opposite sign

$$\lambda = -\frac{R}{2} (= -4\pi k\rho). \quad (9)$$

Using time-like and null vectors a reasonable definition of time direction is introduced, but it is found that no time coordinate at each space-time point exists which increases as one moves in a positive time-like direction. Einstein in his reply [15] very clearly recognizes the difficulty of incorporating time ordering in relativity, but insists on the necessity of a signal to define time. Regarding Godel's solution he asks whether these are acceptable on physical grounds. Unfortunately there is no physical or mathematical criterion to choose a field equation like (8) amongst many possible field equations; and even if one settles down to a definite field equation there exist arbitrary large number of solutions of the field equation. In view of the idea of the absolute time T we conclude that time in GR is not physical time. Newtonian absolute time is regarded as a metaphysical concept by Cajori [1] but T discussed here has physical reality. Profound consequences follow from this idea as shown in a recent monograph [16]. Here we limit our discussion to its implications in the context of AAD. By its very nature universality of time T in the whole of the universe implies space continuum, and instantaneous action. Thus the space could be viewed as a medium in Newtonian sense, and if the meaning of AAD is understood to be the absence of a medium then this action is instantaneous but not AAD. In what form does this action manifest in the universe? In [12] it was suggested that gravitation as an apparent force originates due to inhomogeneous distribution of spatial structures and the expansion of the universe. Therefore, identifying gravitation with this action, we arrive at the conclusion that gravitation

is an instantaneous action. Let us now consider the electromagnetic force. The first significant out-come of our space-time analysis is that the nature of source i.e. electric charge can be understood in mechanical terms. This becomes possible with the belief that cosmic process is replicated at sub-atomic level, and the observation that the electric charge occurs as e^2 once the field quantities are expressed in geometrical units (for example electric field in the unit of length^{-2}). That large scale structure of universe has some deep connection with the atomic structure is a belief shared by many physicists, notably by Eddington as pointed out by Infeld in [15]. Einstein rejected it but recent unified theories also seem to indicate this connection. A space-time model is envisaged such that “spatio-temporal” bounded structures possess spinning motion and translation in space (corresponding to rotation and expansion of the universe respectively). Noting that the dimension of e^2/c is that of angular momentum, we can formulate a direct particle interaction theory for electromagnetism. The localized space-time structures approximated as isolated objects are defined to be the particles, e.g. electron and photon. Electron-electron or electron-photon interaction is a direct particle contact interaction (collision) not action-at-a-distance, and there is no self field associated with them. External electric or magnetic fields represent a kind of photon fluid. Two electrons immersed in such a photon fluid placed a distance apart transmit the disturbance caused by their spinning motion through the fluid, and influence each other. This interaction is therefore not instantaneous. Since this approach is radically different than the standard electromagnetism, there are many open problems in it though some progress has been made and we refer the reader to [16]. I believe alternative paradigm for fundamental physics propounded here deserves attention to resolve the debatable issues such as instantaneous AAD versus field theory.

Acknowledgments

I am grateful to Dr. R. Smirnov-Rueda for inviting me to write this essay which proved to be a rewarding experience. Library facility at the Banaras Hindu University is acknowledged.
